Bit Strings

Find a recurrence relation and give initial conditions for the number of bit strings of length *n* that do <u>not have two consecutive 0s</u>. How many such bit strings are there of length five?

Number of bit strings of length n with no two consecutive 0s:

Any bit string of length n-1 with no two consecutive 0s

1 a_{n-1} Any bit string of length n-2 with no two consecutive 0s

1 0 a_{n-2} Total: $a_n = a_{n-1} + a_{n-2}$

Recurrence Relations

- A recurrence relation (R.R., or just recurrence) for a sequence $\{a_n\}$ is an equation that expresses a_n in terms of one or more previous elements a_0, \ldots, a_{n-1} of the sequence, for all $n \ge n_0$.
 - A recursive definition, without the base cases.
- A particular sequence (described non-recursively) is said to *solve* the given recurrence relation if it is consistent with the definition of the recurrence.
 - A given recurrence relation may have many solutions.

Recurrence Relation Example

Consider the recurrence relation

$$a_n = 2a_{n-1} - a_{n-2} \quad (n \ge 2).$$

Which of the following are solutions?

$$a_n = 3n$$
 Yes
 $a_n = 2^n$ No
 $a_n = 5$ Yes

2*3(n-1)-3(n-2)=6n-6-3n+6=3n.

$$\chi^2 = 2\chi - |$$

Remember

- To define a sequence recursively, a recursive formula must be accompanied by information about the beginning of the sequence.
- This information is called the initial condition (初始条件) or conditions for the sequence.

Solving Tower of Hanoi RR

$$H_{n} = 2 H_{n-1} + 1$$

$$= 2 (2 H_{n-2} + 1) + 1 = 2^{2} H_{n-2} + 2 + 1$$

$$= 2^{2} (2 H_{n-3} + 1) + 2 + 1 = 2^{3} H_{n-3} + 2^{2} + 2 + 1$$
...
$$= 2^{n-1} H_{1} + 2^{n-2} + \dots + 2 + 1$$

$$= 2^{n-1} + 2^{n-2} + \dots + 2 + 1 \quad \text{(since } H_{1} = 1\text{)}$$

$$= \sum_{i=0}^{n-1} 2^{i}$$

$$= 2^{n} - 1 \quad \text{(From } \sum_{j=0}^{n} ar^{j} = \frac{ar^{n+1} - a}{r - 1}, \text{ where } a = 1, r = 2\text{)}$$

Example Applications

Recurrence relation for growth of a bank account with P% interest per given period:

$$M_n = M_{n-1} + (P/100)M_{n-1}$$

 Growth of a population in which each organism yields 1 new one every period starting 2 periods after its birth.

$$P_n = P_{n-1} + P_{n-2}$$
 (Fibonacci relation)

Solving Compound Interest RR

Divide-and-Conquer Recurrence Relations

- Suppose that a recursive algorithm divides a problem of size *n* into *a* subproblems.
- Assume each subproblem is of size n/b.
- Suppose g(n) extra operations are needed in the conquer step.
- Then *f*(*n*) represents the number of operations to solve a problem of size *n* satisfies the following recurrence relation:

$$f(n) = af(n/b) + g(n)$$

This is called a divide-and-conquer recurrence relation.

Examples

- Binary search: Break list into 1 subproblem (smaller list) (so a=1) of size $\leq \lceil n/2 \rceil$ (so b=2).
 - So $T(n) = T(\lceil n/2 \rceil) + c$ (g(n) = c constant)
- Merge sort: Break list of length n into 2 sublists (a=2), each of size $\leq \lceil n/2 \rceil$ (so b=2), then merge them, in $g(n) = \Theta(n)$ time.
 - So $T(n) = 2T(\lceil n/2 \rceil) + n$

Conquer Recurrence Relations

$$f(n) = af(n/b) + g(n)$$

$$= a^{2}f(n/b^{2}) + ag(n/b) + g(n)$$

$$= a^{3}f(n/b^{3}) + a^{2}g(n/b^{2}) + ag(n/b) + g(n)$$
...
$$= a^{\log_{b} n} f(1) + \sum_{i=0}^{\log_{b} n-1} a^{i}g(n/bi)$$

Theorem 1

Let f be an increasing function that satisfies the recurrence relation f(n) = af(n/b) + c

whenever n is divisible by b, where $a \ge 1$, b is an integer greater than 1, and c is a positive real number. Then f(n) is $\begin{cases} O(n^{\log_b a}) & \text{if } a > 1 \\ O(\log n) & \text{if } a = 1. \end{cases}$

Furthermore, when $n = b^k$ and $a \ne 1$, where k is a positive integer, $f(n) = C_1 n^{\log_b a} + C_2$ where $C_1 = f(1) + c/(a-1)$ and $C_2 = -c/(a-1)$.

proof (1)

•
$$f(n) = a^{\log_b n} f(1) + \sum_{j=0}^{\log_b n-1} a^j g(n/bj)$$

• let g(n)=c,

$$f(n) = a^{\log_b n} f(1) + \sum_{j=0}^{\log_b n-1} a^j c$$

when a=1, $f(n)=f(1)+c\log_b n$.

Therefore, f(n) is $O(log_b n)$ when a=1.

proof (2)

when a>1,

$$f(n) = a^{\log_b n} f(1) + c \sum_{j=0}^{\log_b n-1} a^j$$

$$= a^{\log_b n} f(1) + c(a^{\log_b n} - 1)/(a-1)$$

$$= a^{\log_b n} (f(1) + c/(a-1)) - c/(a-1)$$

$$= C_1 n^{\log_b a} + C_2 \text{ because } a^{\log_b n} = n^{\log_b a}$$
Therefore, $f(n)$ is $O(n^{\log_b a})$ when $a > 1$.

Example 7

Give a big-O estimate for the number of comparisons used by a binary search.

Solution: Since the number of comparisons used by binary search is f(n) = f(n/2) + c where n is even, by Theorem 1, it follows that f(n) is $O(\log_2 n)$.

The Master Theorem

Consider a function f(n) that, for all $n=b^k$ for all $k \in \mathbb{Z}^+$, satisfies the recurrence relation:

$$f(n) = af(n/b) + cn^d$$

with $a \ge 1$, integer b > 1, real c > 0, $d \ge 0$. Then:

$$f(n) \in \begin{cases} O(n^d) & \text{if } a < b^d \\ O(n^d \log n) & \text{if } a = b^d \\ O(n^{\log_b a}) & \text{if } a > b^d \end{cases}$$

Proof: f(n) = af(n|b) + cnd

- $f(n) = a^{\log_b n} f(1) + \sum_{i=0}^{\log_b n-1} a^i g(n/bj)$
- let $g(n)=cn^d$, $k=log_k n$,

$$f(n) = a^{k} f(1) + c \sum_{j=0}^{k-1} a^{j} \left(\frac{n}{b^{j}}\right)^{d}$$

$$= a^{k} f(1) + c \sum_{j=0}^{k-1} n^{d} \left(\frac{a}{b^{d}}\right)^{j}$$

$$= a^{k} f(1) + c n^{d} \sum_{j=0}^{k-1} \left(\frac{a}{b^{d}}\right)^{j}$$

Proof(2)

If $a = b^d$, then $log_b a = d$, $f(n) = a^k f(1) + c \sum_{j=0}^{k-1} n^d$ $= a^k f(1) + kcn^d$ $= n^{log} b^a f(1) + c(log_b n) n^d$ $= n^d f(1) + c n^d log_b n.$ Hence, f(n) is $O(n^d log n)$.

Proof(3)

If $a \neq b^d$,

$$f(n) = a^{k}f(1) + c n^{d} \sum_{j=0}^{k-1} \left(\frac{a}{b^{d}}\right)^{j}$$

$$= a^{k}f(1) + cn^{d} \frac{(a/b^{d})^{k} - 1}{(a/b^{d}) - 1} \quad (b^{dk} = b^{\log_{b}n^{d}} = n^{d}.)$$

$$= a^{k}f(1) + cn^{d} \frac{b^{d}(a^{k}/n^{d} - 1)}{a - b^{d}}$$

$$= a^{k}f(1) + \frac{b^{d}c}{a - b^{d}}a^{k} - \frac{b^{d}c}{a - bd}n^{d}$$

$$Hence, f(n) = C_{1}n^{d} + C_{2}n^{\log_{b}a}.$$

Proof(4)

- If $a < b^d$, then $log_b a < d$, so $O(C_1 n^d + C_2 n^{log} b^a) => O(n^d)$.
- If $a > b^d$, then $log_b a > d$, so $O(C_1 n^d + C_2 n^{log} b^a) => O(n^{log} b^a)$.

Example: Mergesort

- T(n) = 2*T(n/2)+n
 - a=2,b=2,d=1;
 - As $a=b^d$, $T(n)=O(n\log_2 n)$
 - Check:
 - $2 T(n/2) + n = 2 (n/2 \log_2(n/2)) + n$ = $n \log_2(n/2) + n$ = $n \log_2(n) - n \log_2 2 + n$ = $n \log_2(n) - n + n$ = $n \log_2(n)$

8.2: Solving Recurrences

■ A <u>linear homogeneous recurrence of degree k</u> with <u>constant coefficients</u> ("k-LiHoReCoCo",k阶定常系数 线性齐次递推关系) is a recurrence of the form $a_n = c_1 a_{n-1} + ... + c_k a_{n-k}$,

 $a_n = c_1 a_{n-1} + \ldots + c_k a_{n-k}$, where the $c_{i,}$ $(i = 1, \ldots, k)$ are all real, and $c_k \neq 0$.

- Note
 - The solution is uniquely determined if k initial conditions $a_0...a_{k-1}$ are provided.

Examples

- $P_n = (1.11)P_{n-1}$ linear homogeneous recurrence relation of degree one
- $f_n = f_{n-1} + f_{n-2}$ linear homogeneous recurrence relation of degree two
- $a_n = a_{n-1} + a_{n-2}^2$ not linear
- $\blacksquare H_n = 2H_{n-1} + 1$ not homogeneous
- \blacksquare $B_n = nB_{n-1}$ coefficients are not constants

Solving LiHoReCoCos

- Basic idea: Look for solutions of the form $a_n = r^n$, where r is a constant.
- This requires the *characteristic equation*:

$$r^{n} = c_{1}r^{n-1} + \dots + c_{k}r^{n-k}, i.e.,$$

 $r^{k} - c_{1}r^{k-1} - \dots - c_{k-1}r - c_{k} = 0$

■ The solutions (*characteristic roots*) can yield an explicit formula for the sequence.

Solving 2-LiHoReCoCos

Consider an arbitrary 2-LiHoReCoCo:

$$a_n = c_1 a_{n-1} + c_2 a_{n-2}$$

■ It has the characteristic equation (C.E.):

$$r^2 - c_1 r - c_2 = 0$$

■ **Theroem 1:** If this CE has 2 roots $r_1 \neq r_2$, then

$$a_n = \alpha_1 r_1^n + \alpha_2 r_2^n$$
 for $n \ge 0$ for some constants α_1 , α_2 .

Proof(1)

- Suppose that r_1 and r_2 are roots of $x^2 c_1 x c_2 = 0$, so $r_1^2 c_1 r_1 c_2 = 0$, $r_2^2 c_1 r_2 c_2 = 0$ and then $a_n = a_1$ $r_1^n + a_2 r_2^n$, for $n \ge 1$.
- We show that this definition of a_n defines the same sequence as $a_n = c_1 a_{n-1} + c_2 a_{n-2}$
- First we note that α_1 and α_2 are chosen so that $a_1 = \alpha_1 r_1 + \alpha_2 r_2$ and $a_2 = \alpha_1 r_1^2 + \alpha_2 r_2^2$ and so the initial conditions are satisfied. Then

Proof(2)

$$a_{n} = \alpha_{1}r_{1}^{n} + \alpha_{2}r_{2}^{n}$$

$$= \alpha_{1}r_{1}^{n-2}r_{1}^{2} + \alpha_{2}r_{2}^{n-2}r_{2}^{2}$$

$$= \alpha_{1}r_{1}^{n-2}(c_{1}r_{1} + c_{2}) + \alpha_{2}r_{2}^{n-2}(c_{1}r_{2} + c_{2})$$

$$= c_{1}\alpha_{1}r_{1}^{n-1} + c_{2}\alpha_{1}r_{1}^{n-2} + c_{1}\alpha_{2}r_{2}^{n-1} + c_{2}\alpha_{2}r_{2}^{n-2}$$

$$= c_{1}(\alpha_{1}r_{1}^{n-1} + \alpha_{2}r_{2}^{n-1}) + c_{2}(\alpha_{1}r_{1}^{n-2} + \alpha_{2}r_{2}^{n-2})$$

$$= c_{1}a_{n-1} + c_{2}a_{n-2}$$

Proof(3)

$$a_0 = C_0 = \alpha_1 + \alpha_2, \quad a_1 = C_1 = \alpha_1 r_1 + \alpha_2 r_2.$$

$$\alpha_2 = C_0 - \alpha_1.$$

$$C_1 = \alpha_1 r_1 + (C_0 - \alpha_1) r_2.$$
 Hence, $C_1 = \alpha_1 (r_1 - r_2) + C_0 r_2.$

$$\alpha_1 = \frac{C_1 - C_0 r_2}{r_1 - r_2}$$

$$\alpha_2 = C_0 - \alpha_1 = C_0 - \frac{C_1 - C_0 r_2}{r_1 - r_2} = \frac{C_0 r_1 - C_1}{r_1 - r_2}$$

Example 3

- Solve the recurrence $a_n = a_{n-1} + 2a_{n-2}$ given the initial conditions $a_0 = 2$, $a_1 = 7$.
- Solution: Use theorem 1
 - $c_1 = 1, c_2 = 2$
 - Characteristic equation: $r^2 r 2 = 0$
 - Solutions: $r = [-(-1) \pm ((-1)^2 4 \cdot 1 \cdot (-2))^{1/2}] / 2 \cdot 1$ = $(1 \pm 9^{1/2})/2 = (1 \pm 3)/2$, so r = 2 or r = -1.
 - So $a_n = \alpha_1 2^n + \alpha_2 (-1)^n$.

Example 3 Continued...

To find a_1 and a_2 , solve the equations for the initial conditions a_0 and a_1 :

$$a_0 = 2 = \alpha_1 2^0 + \alpha_2 (-1)^0
 a_1 = 7 = \alpha_1 2^1 + \alpha_2 (-1)^1$$

Simplifying, we have the pair of equations:

$$2 = \alpha_1 + \alpha_2$$
$$7 = 2\alpha_1 - \alpha_2$$

which we can solve easily by substitution:

$$\alpha_2 = 2 - \alpha_1; \quad 7 = 2\alpha_1 - (2 - \alpha_1) = 3\alpha_1 - 2;$$

 $9 = 3\alpha_1; \quad \alpha_1 = 3; \quad \alpha_2 = -1.$

Final answer: $a_n = 3 \cdot 2^n - (-1)^n$

Check:
$$\{a_{n>0}\}=2, 7, 11, 25, 47, 97...$$

Example 4

- The Fibonacci sequence is defined by a linear homogeneous recurrence relation of degree 2, so by Theorem 1, the roots of the associated equation are needed to describe the explicit formula for the sequence.
- From $f_n = f_{n-1} + f_{n-2}$ and $f_1 = f_2 = 1$, we have $x^2 x 1 = 0$.
- Using the quadratic formula to obtain the roots.

$$r_1 = \frac{1 + \sqrt{5}}{2}$$
 $r_2 = \frac{1 - \sqrt{5}}{2}$

Fibonacci Numbers (continued)

Therefore by Theorem 1

$$f_n = \alpha_1 \left(\frac{1 + \sqrt{5}}{2} \right)^n + \alpha_2 \left(\frac{1 - \sqrt{5}}{2} \right)^n$$

for some constants α_1 and α_2 .

Using the initial conditions $f_0=0$ and $f_1=1$, we have

$$f_1 = \alpha_1 \left(\frac{1 + \sqrt{5}}{2} \right) + \alpha_2 \left(\frac{1 - \sqrt{5}}{2} \right) = 1$$

Solving, we obtain $\alpha_1 = \frac{1}{\sqrt{5}}$, $\alpha_2 = -\frac{1}{\sqrt{5}}$ Hence,

$$f_n = \frac{1}{\sqrt{5}} \left(\frac{1+\sqrt{5}}{2} \right)^n - \frac{1}{\sqrt{5}} \left(\frac{1-\sqrt{5}}{2} \right)^n$$

The Case of Degenerate Roots

- Now, what if the C.E. $r^2 c_1 r c_2 = 0$ has only 1 root r_0 ?
- Theorem 2: Then $a_n = \alpha_1 r_0^n + \alpha_2 n r_0^n, \text{ for all } n \ge 0,$ for some constants α_1, α_2 .

Theroem 2 proof(1)

- Suppose that r_0 is only root of $x^2 c_1 x c_2 = 0$, so $r_0^2 c_1 r_0 c_2 = 0$ and then $a_n = a_1 r_0^n + a_2 n r_0^n$, for $n \ge 1$.
- $a_1 r_0^n + \alpha_2 n r_0^n = \alpha_1 r_0^2 r_0^{n-2} + \alpha_2 n r_0^2 r_0^{n-2}$ $= \alpha_1 (c_1 r_0 + c_2) r_0^{n-2} + \alpha_2 n (c_1 r_0 + c_2) r_0^{n-2}$ $= \alpha_1 c_1 r_0^{n-1} + \alpha_1 c_2 r_0^{n-2} + \alpha_2 n c_1 r_0^{n-1} + \alpha_2 n c_2 r_0^{n-2}$ $= c_1 (\alpha_1 r_0^{n-1} + \alpha_2 n r_0^{n-1}) + c_2 (\alpha_1 r_0^{n-2} + \alpha_2 n r_0^{n-2})$ $= c_1 a_{n-1} + c_2 a_{n-2}$

Theroem 2 proof(2)

$$a_0 = C_0 = \alpha_1 + \alpha_2 n, \quad a_1 = C_1 = \alpha_1 r_0 + \alpha_2 n r_0.$$

$$C_1 = \alpha_1 r_0 + (C_0 - \alpha_1) r_0 / n.$$

- $Hence, C_1 = (n-1)\alpha_1 r_0 / n + C_0 r_0 / n$.
- $\alpha_1 = (nC_1 C_0 r_0) / (n-1)r_0$

Example 5

Find solution of recurrence relation

$$a_n = 6a_{n-1}$$
 -9 a_{n-2} with initial condition $a_0=1$, $a_1=6$
The only root of r^2 - $6r + 9 = 0$ is $r = 3$.
Hence $a_n = \alpha_1 3^n + \alpha_2 n 3^n$
From initial conditions, $a_0=1=\alpha_1$.

From initial conditions,
$$a_0=1=\alpha_1$$
, $a_1=6=\alpha_1*3+\alpha_2*3$

$$\alpha_1 = 1$$
 and $\alpha_2 = 1$
Therefore, $a_n = 3^n + n3^n$

k-LiHoReCoCos

- Consider a k-LiHoReCoCo:
- It's C.E. is: $r^k \sum_{i=0}^k c_i r^{k-i} = 0$
- **Thm.3:** If this has k distinct roots r_i , then the solutions to the recurrence $a_n = \sum_{i=1}^k c_i a_{n-i}$ are of the form: $a_n = \sum_{i=1}^k \alpha_i r_i^n$

$$a_n = \sum_{i=1}^k \alpha_i r_i^n$$

for all $n \ge 0$, where the α_i are constants.

Example 6

- Find the solution to the recurrence relation $a_n = 6a_{n-1}-11$ $a_{n-2}+6a_{n-3}$ with the initial condition $a_0=2, a_1=5$, and $a_2=15$
- $r^3 6r^2 + 11r 6 = 0 = r = 1, r = 2, and r = 3$
- $a_n = \alpha_1 \cdot 1^n + \alpha_2 \cdot 2^n + \alpha_3 \cdot 3^n.$
- $a_0 = 2 = \alpha_1 + \alpha_2 + \alpha_3, \ a_1 = 5 = \alpha_1 + \alpha_2 \cdot 2 + \alpha_3 \cdot 3,$ $a_2 = 15 = \alpha_1 + \alpha_2 \cdot 4 + \alpha_3 \cdot 9.$
- $\alpha_1 = 1$, $\alpha_2 = -1$, and $\alpha_3 = 2$. Hence, the unique solution to this recurrence relation and the given initial conditions is the sequence $\{an\}$ with $an = 1-2^n + 2 \cdot 3^n$.

Example of complex roots

38. a) Find the characteristic roots of the linear homogeneous recurrence relation

$$a_{\rm n} = 2a_{\rm n-1} - 2a_{\rm n-2}.$$

[Note: These are complex numbers.]

b) Find the solution of the recurrence relation in part (a) with $a_0 = 1$ and $a_1 = 2$.

solution:

a) The characteristic equation is $r^2 - 2r + 2 = 0$, whose roots are, by the quadratic formula, $1 \pm \sqrt{-1}$, in other words, 1 + i and 1 - i.

Solution:

b) The general solution is, by part (a),

$$a_n = \alpha 1(1+i)^n + \alpha 2(1-i)^n$$
.

Plugging in the initial conditions gives us $1 = \alpha 1 + \alpha 2$ and $2 = (1 + i)\alpha 1 + (1 - i)\alpha 2$.

Solving these linear equations tells us that

$$\alpha 1 = 1/2 - 1/2*i$$
 and $\alpha 2 = 1/2 + 1/2*i$.

Therefore the solution is

$$a_n = (1/2 - 1/2*i)(1+i)^n + (1/2+1/2*i)(1-i)^n$$
.

Lin

- 39. a) Find the characteristic roots of the linear homogeneous recurrence relation $a_n = a_{n-4}$. [Note: These include complex numbers.]
- b) Find the solution of the recurrence relation in part (a) with $a_0 = 1$, $a_1 = 0$, $a_2 = -1$, and $a_3 = 1$
- solution:
- \bullet a) 1, -1, i, -i
- b) $a_n = 1/4 1/4 * (-1)^n + (2+i)/4 * (i^n) + (2-i)/4 *$

an= an-1+ anz+any+amp.

$$((-i)^n)$$
 $\chi^2 \pm 1$ $\chi = \pm 1$, ± 1

Degenerate *k*-LiHoReCoCos

Suppose there are t roots $r_1, ..., r_t$ with multiplicities $m_1, ..., m_t$. Then: $a_n = \sum_{i=1}^t \left(\sum_{j=0}^{m_i-1} \alpha_{i,j} n^j\right) r_i^n$

for all $n \ge 0$, where all the α are constants.

$$a_n = (\alpha_{1,0} + \alpha_{1,1}n + \dots + \alpha_{1,m_1-1}n^{m_1-1})r_1^n$$

$$+ (\alpha_{2,0} + \alpha_{2,1}n + \dots + \alpha_{2,m_2-1}n^{m_2-1})r_2^n$$

$$+ \dots + (\alpha_{t,0} + \alpha_{t,1}n + \dots + \alpha_{t,m_t-1}n^{m_t-1})r_t^n$$

an= a, + d2(-1)"+ d22"+ d4(-2)"

Example 8

- Find the solution to the recurrence relation $a_n=-3a_{n-1}-3a_{n-2}-a_{n-3}$ with the initial condition $a_0=1,a_1=-2,$ and $a_2=-1$.
- Solution: $r^3 + 3r^2 + 3r + 1 = 0$. =>r = -1
- $a_n = \alpha_{1,0}(-1)^n + \alpha_{1,1}n(-1)^n + \alpha_{1,2}n^2(-1)^n.$
- $a_0 = 1 = \alpha_{1,0}, \ a_1 = -2 = -\alpha_{1,0} \alpha_{1,1} \alpha_{1,2},$

$$a_2 = -1 = \alpha_{1,0} + 2\alpha_{1,1} + 4\alpha_{1,2}.$$

- $\alpha_{1,0} = 1$, $\alpha_{1,1} = 3$, and $\alpha_{1,2} = -2$.
- $a_n = (1+3n-2n^2)(-1)^n$.

(ditain) rn

Linear Nonhomogeneous Recurrence Relations with Constant Coefficients

Definition: A linear nonhomogeneous recurrence relation with constant coefficients is a recurrence relation of the form:

$$a_n = c_1 a_{n-1} + c_2 a_{n-2} + \dots + c_k a_{n-k} + F(n)$$

where c_1 , c_2 ,, c_k are real numbers, and F(n) is a function not identically zero depending only on n.

The recurrence relation

$$a_n = c_1 a_{n-1} + c_2 a_{n-2} + \dots + c_k a_{n-k}$$

is called the associated homogeneous recurrence relation.

Linear Nonhomogeneous Recurrence Relations with Constant Coefficients (cont.)

The following are linear nonhomogeneous recurrence relations with constant coefficients:

$$a_n = a_{n-1} + 2^n$$
,
 $a_n = a_{n-1} + a_{n-2} + n^2 + n + 1$,
 $a_n = 3a_{n-1} + n3^n$,
 $a_n = a_{n-1} + a_{n-2} + a_{n-3} + n!$

where the following are the associated linear homogeneous recurrence relations, respectively:

$$\begin{aligned} a_n &= a_{n-1} \;, \\ a_n &= a_{n-1} + a_{n-2}, \\ a_n &= 3a_{n-1} \;, \\ a_n &= a_{n-1} + a_{n-2} + a_{n-3} \end{aligned}$$

Solving Linear Nonhomogeneous Recurrence Relations with Constant Coefficients

Theorem 5: If $\{a_n^{(p)}\}$ is a particular solution of the nonhomogeneous linear recurrence relation with constant coefficients

 $a_n = c_1 a_{n-1} + c_2 a_{n-2} + \cdots + c_k a_{n-k} + F(n)$, then every solution is of the form $\{a_n^{(p)} + a_n^{(h)}\}$, where $\{a_n^{(h)}\}$ is a solution of the associated homogeneous recurrence relation

$$a_n = c_1 a_{n-1} + c_2 a_{n-2} + \dots + c_k a_{n-k}$$

Proof: Because $\{a_n^{(p)}\}$ is a particular solution of the nonhomogeneous recurrence relation, we know that

$$a_n^{(p)} = c_1 a_{n-1}^{(p)} + c_2 a_{n-2}^{(p)} + \dots + c_k a_{n-k}^{(p)} + F(n).$$

Now suppose that $\{b_n\}$ is a second solution of the nonhomogeneous recurrence relation, so that

$$b_n = c_1 b_{n-1} + c_2 b_{n-2} + \cdots + c_k b_{n-k} + F(n).$$

Subtracting the first of these two equations from the second shows that

$$b_n - a_n^{(p)} = c_1(b_{n-1} - a_{n-1}^{(p)}) + c_2(b_{n-2} - a_{n-2}^{(p)}) + \dots + c_k(b_{n-k} - a_{n-k}^{(p)}).$$

It follows that $\{b_n - a_n^p\}$ is a solution of the associated homogeneous linear recurrence, say, $\{a_n^{(h)}\}$. Consequently, $b_n = a_n^{(p)} + a_n^{(h)}$ for all n.

Example 10

- Find all solutions to $a_n = 3a_{n-1} + 2n$. Which solution has $a_1 = 3$?
 - Its associated 1-LiHoReCoCo is $a_n = 3a_{n-1}$, whose solutions are all of the form $a_n^{(h)} = \alpha 3^n$.
 - Thus the solutions to the original problem are all of the form $a_n = a_n^{(p)} + \alpha 3^n$. So, all we need to do is find one $a_n^{(p)}$ that works.

Trial Solutions

- If the extra terms F(n) are a degree-t polynomial in n, you should try a degree-t polynomial as the particular solution $a_n^{(p)}$.
- This case: F(n) is linear so try $a_n^{(p)} = cn + d$.

$$cn+d = 3(c(n-1)+d) + 2n$$
 (for all n)
 $(-2c-2)n + (3c-2d) = 0$ (collect terms)
then $2+2c=0$ and $3c-2d=0$.

So
$$c = -1$$
 and $d = -3/2$.

So
$$a_n^{(p)} = -n - 3/2$$
 is a solution.

Check:
$$3 a_{n-1}^{(p)} + 2n = 3(-(n-1)-3/2) + 2n = \dots = -n-3/2.$$

Finding a Desired Solution

• From the previous, we know that all general solutions to our example are of the form:

$$a_n = -n - 3/2 + \alpha 3^n$$
.

Solve this for α for the given case, $a_1 = 3$:

$$3 = -1 - 3/2 + \alpha 3^{1}$$

 $\alpha = 11/6$

• The answer is $a_n = -n - 3/2 + (11/6)3^n$.
